

Phishing Website Simulation

Kaleb Henderson, Hussain Reza

This project will simulate a phishing website in a controlled environment to demonstrate how attackers replicate legitimate login pages to capture user credentials. The simulation will not target real users and will not collect real credentials. The methodology behind this is as follows:

- Create a fake login webpage
- Implement credential capture locally
- Host in a VM
- Demonstrate detection
- Add defensive recommendations

Deliverables we will provide are as follows:

- Working phishing simulation in a lab environment
- Screenshot evidence of credential capture
- Analysis of why users are vulnerable
- Technical explanation of how the attack works

Tools:

- HTML
- Python
- VM
- Wireshark if applicable

Phishing is a social engineering problem which is the real exploit. The same techniques that make phishing effective are the same techniques used in marketing funnels and persuasion. With our project we will provide evidence of how simple it is to fall for said exploit, along with how simple it is to “avoid” it.
